

Energy storage high-voltage box pre-charging circuit

Why do high-voltage systems use precharged circuits?

This is due to the initial charging current of the input capacitances of the circuit. Failure to manage inrush current can lead to damaged cables, connectors, or fuses. High-voltage systems (100V+) often use precharged circuits to limit inrush current. This process protects the system from damage, extends lifespan, and increases reliability.

What is a pre-charge state in a HV battery?

The HV battery is disconnected from the load at both terminals and the DC link capacitor remains discharged. Pre-charging introduces a new state in the system, which we will call the pre-charge state. In the pre-charge state, the pre-charge contactor and the HV negative contactor are closed as shown in Figure 2.

What is a pre-charge circuit?

Applications and Benefits Pre-charge circuits are often used in electric vehicles (EVs) such as battery management systems, onboard chargers, and in industrial applications such as power supplies and power distribution units. In EVs, controllers with high capacitive loads regulate motors.

How does pre-charging work?

Unlike in systems without pre-charging, during a pre-charging process, system voltage rises relatively slowly and in a controlled manner. As voltage rises to reach a steady state, pre-charging is no longer needed. It can be taken out of the circuit, normally through some automatic method.

How does a precharge circuit work?

A precharge circuit charges the DC-link capacitor to the battery voltage, minimizing the inrush current caused when the main contactors close. For the health of the main contactors the inrush is minimized as too high of inrush can cause the contacts to weld together, rendering them defective. Figure 1-1. Precharge Configurations

What is the electrical design of a battery pack?

The electrical design of the battery pack is associated with fundamental electrical elements. These elements are: Busbars,Contactors,Fuses,pre-charge resistors,current sensors,HV (High Voltage) and LV (Low Voltage) Connectors,and wiring harnesses. This will cover: For all of these components we need to consider:

High voltage power board: TP-HVP01A: The high-voltage power board (HVP) is the core component in the household storage stack-high-voltage box, which integrates fuses, shunts, pre-charging, high-voltage acquisition circuits, DCDC, ...

A pre-charge circuit can be used to prevent stress and damage to the electric system by implementing a resistor and a switch to limit in-rush current. The TPSI3050-Q1 can replace traditional pre-charged contactors
