

How much force does a wind turbine blade have

What forces affect wind turbine blades?

The blades of a wind turbine are affected by four forces: drag, lift, centrifugal, and gravitational forces. Drag forces are caused by the air molecules that hit the surface of the blade facing the wind. A major component of the drag force acts in the direction that is parallel to the main shaft of the rotor.

What is a wind turbine force?

where P is the power, F is the force vector, and v is the velocity of the moving wind turbine part. The force F is generated by the wind's interaction with the blade. The magnitude and distribution of this force is the primary focus of wind-turbine aerodynamics. The most familiar type of aerodynamic force is drag.

Why do wind turbines have more blades?

When wind passes over a turbine blade, it creates a drag force that slows it down. This drag force is proportional to the surface area of the blade. Having more blades means more surface area for the wind to hit, creating more drag, slowing down the rotating speed, and reducing the turbine's efficiency.

How do wind turbine blades reduce drag?

To reduce drag, blades are made relatively narrow. A typical drag coefficient for wind turbine blades is 0.04; compare this to a well-designed automobile with a drag coefficient of 0.30. Even though the drag coefficient for a blade is fairly constant, as the wind speed increases, the amount of drag force also increases.

What happens when a wind turbine blade rotates?

Assume the flat part of the blade is facing the true wind. As the blade turns, air that flows across the leading edge appears as a separate component of the wind; thus, the apparent wind direction is shifted to oppose the direction of rotation. The rotation of the blade causes a lift force that is perpendicular to the apparent wind direction.

What is wind-turbine aerodynamics?

The magnitude and distribution of this force is the primary focus of wind-turbine aerodynamics. The most familiar type of aerodynamic force is drag. The direction of the drag force is parallel to the relative wind. Typically, the wind turbine parts are moving, altering the flow around the part.
